TITLE: Local spectral analysis

PERIODICAL: Ukrayins'kyy fizychnyy zhurnal, v. 6, no. 6, 1961,

861 - 866

TEXT: The development of local spectral analysis for steel is of great importance for study of changes in concentration during diffuse saturation of metals, for the study of gaseous erosion, friction etc. The authors developed a method of local quantitative spectral analysis of carbon in steels (as well as of some other elements), for studying diffusion processes during the action of powder gases on the metal. In such a method of spectral analysis, great accuracy of electrode mounting is required. For this purpose, the authors designed a special support which provides for the required accuracy and also permits carrying out the analysis when the specimen is in motion. In earlier experiments it was found that the most convenient size of the discharge gap was 0,7 mm. The choice of ✓

D299/D304

Local spectral analysis

optimal exposure is also important in the spectral analysis of the carbon content in steel. It was found that with long exposures on the spectrograph KCA-1 (KSA-1) (which has large dispersion), the ratio of blackening of the carbon- to iron lines is half the corresponding value for the spectrograph ИСП-28 (ISP-28) (with medium dispersion). Therefore, it can be assumed that in this case diffusion processes in the discharge gap have an important role. Another significant factor in determining the carbon content is the type of support electrode. Best results were obtained with a magnesium electrode; it was found that in this case the specimen surface is much more even than with electrodes of other material. The electrode diameter is also a factor to be taken into account; if the diameter exceeds 1.8 mm, the specimen surface becomes uneven, the surfaces were most even, for a diameter of 1.4 mm. The method of removal of the layers which were already treated by the discharge, is also very important in local spectral analysis. The experiments were conducted on steel specimens XI2M (KhI2M), which have 2 structural components: Sorbite and carbide, with greatly divergent physico-mechanical properties. The specimens were treated differently, (abrasive).

sion and polishing). Protuberances were observed on the polished surface; a metallographic investigation showed that these were carbides. Specimens of steel 20 and γ -10 (U-10) were analyzed; it was found that even if the powder gases are active for a short time only (0.002 sec.), a considerable saturation with carbon takes place in the surface layer to a depth of 15 μ . The above method was used for studying the diffusion processes during the erosion of piston rings of certain types of internal combustion engines. The atomic carbon which is formed, penetrates the surface layers of the piston rings, forming brittle iron carbide. There are 6 figures and 2 Soviet-bloc references.

TITLE: Investigation of processes occurring in the surface layer of a metal during spectrum analysis

PERIODICAL: Akademiya nauk SSSR. Izvestiya. Seriya fizicheskaya, v. 26, no. 7, 1962, 684-887

TEXT: The entry of carbon from steels into the arc of a discharge was examined with a stereomicroscope, a profilograph, and a spectrograph. It was found to be dependant on the diameter and shape of the magnesium electrode, on the duration of discharge, etc. Investigation of the change in carbon concentration in the surface layer during h-f discharge shows that, particularly in local spectrum analysis, diffusion in the surface layer must be taken into account, and the layer formed during the first picture of the spectrum must be removed before taking a second picture. There are 3 figures.

TITLE: Contact fatigue strength of ShKh15 bearing steel

SOURCE: Tekhnologiya i organizatsiya proizvodstva, no. 3, 1966, 63-66

TOPIC TAGS: fatigue test, fatigue strength, steel microstructure, x-ray analysis,
BEARING STEEL / SHKh15 BEARING STEEL

ABSTRACT: The authors describe a study carried out at the Institute of Mechanics AN UkrSSR in cooperation with the First State Bearing Plant on the contact fatigue strength of ShKh15 bearing steel. The basic criterion in evaluating polishing conditions is taken as the physical state of the layer structure and depth of structural variation. Mechanical methods for testing contact fatigue strength and for measuring microhardness were used together with metallophysical methods and microstructural and x-ray structural analysis. Steel specimens used for these tests were heat treated after finish machining. The following heat treatment procedures were used: quenching at 850°C in 40-50°C oil, cold processing with cooling to -30°C and tempering at 150-160°C. These conditions give specimens with a hardness of HRC 62-64. After heat treatment the specimens were polished under various conditions. The specimens were divided into three groups according to the amount of metal removed: 0.1 mm for the first group; 0.15 mm for the second and 0.25 mm for the third. Depth of structural

Card 1/2

UDC: 620.17:669.14

L 06369-67

ACC NR: AP6027489

variation after polishing for the various groups is the following: 10-30 μ for the first group, 150-170 μ for the second and 220-250 μ for the third. Microstructural analysis for the first group shows that structural variation is not significant. The microhardness of these specimens is 950-1000 kg/mm². X-ray analysis for this group of specimens shows that variations due to polishing and honing are localized in a layer 10-30 μ thick. Slight deformation and elongation of the crystal lattice of the α -phase is observed in this layer. Depth of variation for the second group of specimens is 150-170 μ . This is substantiated by microhardness measurement data and microstructural and x-ray analysis. Depth of variation for the third group reaches 250 μ , these variations being similar to those of the second group. The unetched surfaces of the specimens in the first and second groups examined under an electron microscope show scaly tearing and deep scratches caused by polishing. After etching, secondary solid solutions are observed on individual surfaces oriented in the direction of polishing. A graph is given showing the contact fatigue strength of all three groups. The results show that contact fatigue limit for the second and third groups is identical (150-160 kg/mm²), differing from the first group where maximum contact strength is 200 kg/mm². Pit depth for the first group under staining does not exceed 300 μ , reaching 600-700 μ for the second and third groups. All groups show large-scale microfocal scaling after testing observed on the electron microscope. The authors recommend that polishing procedures be selected which have the minimum effect on the structural variation of the surface layer of ShKh15 steel. Orig. art. has: 4 figures.

TITLE: Effects of the physical condition of the surface layer, formed during grinding, on the contact wear resistance of steel ShKh15

SOURCE: Fiziko-khimicheskaya mekhanika materialov, v. 2, no. 2, 1966, 204-208

TOPIC TAGS: surface fatigue, surface property, metal friction, steel property, grinding wheel, electron microscope, steel, x-ray equipment/ ShKh15 steel, EB60SM2K grinding wheel, E46SM2K grinding wheel, LHM-8M microscope, UEM-100 electron microscope, UPS-50I x-ray equipment

ABSTRACT: The effects of the structure and depth of structural gradients on the surface fatigue of ShKh15 steel were investigated. Thirty-five millimeter diameter x 10-mm thick disc-shaped specimens were heat-treated and ground using wheel EB60SM2K and finish-ground with wheel E46SM2K. Three grinding regimes (0.005 mm/rev, 0.15 mm and 0.25 mm) were used to produce structural changes in layers of 10--20, 150--160, and 220--250 micron respectively. After lapping to an 11--12 class finish, surface fatigue tests were performed at 1750 rpm using methods described by M. A. Puzanov

(Sb. Povysheniye iznosostoykosti detaley mashin, Izd. AN UkrSSR, 1956, No. 22). Microstructural studies of the surface layers were performed using optical and electron microscopes (MIM-8M and UEM-100 respectively) and x-ray equipment (UPS-50I). A discussion of the structural changes for the different grinding regimes is included, and the experimental results are summarized in Fig. 1.

TITLE: Visualization of defects in the lattice of alkali halide crystals with the help of electrolytic coloring

PERIODICAL: Izvestiya Akademii nauk SSSR. Seriya fizicheskaya,
v. 25, no. 3, 1961, 349-350

TEXT: This paper was read at the Ninth Conference on Luminescence (Crystal Phosphors) held in Kiyev from June 20 to June 25, 1960. In the introduction, it is shown that the effect of different kinds of lattice defects on the formation of color centers has been mostly not taken into consideration. It is shown that different kinds of lattice defects are revealed by electrolytic coloring. Since the energies of thermal activation of the ions and of the formation of vacancies at the defects are considerably smaller, the color centers develop there much faster. It is thus possible to observe the defects made visible in a transparent solid body. Defects of various structures were discovered in this manner in the laboratory of the authors. In this connection, it was found that on a

certain heat treatment of alkali halide crystals certain deformations appear, which are in the form of domains and are very similar to those of ferroelectrics. If the crystal is heated to above 500°C and then suddenly cooled to room temperature, the specimen is divided somehow into thin layers parallel to the (110) and (110) planes. The thickness of these layers lies between 0.2 and 0.4 mm. On examination with a polarization microscope in the direction {100}, these were detected in the form of dark and bright bands causing a periodic change in the refraction of light. By coloring, these layers acquire a red or blue color in ordinary light, which shows the existence of color centers of different sizes. It can also be concluded from this fact that in the neighboring twin domains, the lattice is in different states. The coexistence of two lattice modifications having also different coalescence rates of the F-centers leads to the formation of red (odd) and blue (even) centers. The crystals so treated show also a birefringence and a dichroism. Special experiments on NaCl showed that the rate of coagulation depends largely on the static deformations. At the same time, this supports the assumption that the above-mentioned development of layers is a deformation of the crystal domains. There is 1 figure.

into individual twin regions which are differently polarized. The mechanism of the re-orientation of F_2 centers during the process of action of polarized light is discussed. It is also found that colloidal centers can acquire an anisotropic form and orientation in the case of photochemical destruction and under the action of pressure. T. Eksina.

TITLE: Application of the theory of random functions to analysis of the magneto-telluric field

SOURCE: Moscow. Vsesoyuznyy nauchno-issledovatel'skiy Institut geofizicheskikh metodov razvedki. Prikladnaya geofizika, no. 39, 1964, 75-90

TOPIC TAGS: geophysical prospecting, magnetotelluric field, terrestrial electro-magnetic field, electrical prospecting 12

ABSTRACT: Experiments have shown that considerable difficulties are involved in the use of the telluric sounding method. These are due to the inapplicability of the classical methods of spectral expansion to the real magnetotelluric process and field distortions due to the horizontal nonhomogeneity of the medium. These difficulties can be eliminated in part by analysis of quasi-sinusoidal parts of the magnetotelluric process. Whereas, in the simplified modification of magnetotelluric sounding proposed by M. Berdichevskiy (magnetotelluric profiling), such analysis on the whole is satisfactory with respect to the requirements of field work, and magnetotelluric profiling can therefore be used in the field. In magnetotelluric sounding it causes serious limitations which lower the effectiveness of Card 1/2

L 12443-65

O

observations and restrict its field applicability. Elimination of these limitations requires a universal solution of the problem of the spectral expansion of the magnetotelluric process. This paper presents the principles of such a solution on the basis of the theory of random functions and cybernetics. The authors present the classical formulation of the problem, discuss magnetotelluric variations as a random process, illustrate the statistical determination of the parameters of the magnetotelluric field at the surface of a horizontally homogeneous medium, and give a statistical determination of the parameters of the magnetotelluric field at the surface of a horizontally nonhomogeneous medium. It is shown that the statistical parameters of the magnetotelluric field can be determined with complete stability and can be used for a study of the geoelectric cross section. ABSTRACT: This Author Certificate presents a geoelectric prospecting device containing a dc generator, a master oscillator, a thyratron bridge commutator, a reference phase synchropulse shaper unit, a radio station, and a measuring laboratory. The laboratory contains an electromagnetic field receiver, a calibration unit, a selective amplifier, a radio station, a synchropulse shaper unit, an electronic oscillograph, a recorder, a time setting unit, and a detector voltmeter. For generalized utilization of the device in the VP, MPP, and INFAZ methods, to increase the accuracy of measuring the phase angles in the infrasonic frequency range, and to increase the noise

protection when measuring pulsed signals, a phase marker in the form of a diode regenerative comparator is placed in the measuring laboratory. The comparator is connected to the output of the selective amplifier. An input signal divider connected to the input of the selective amplifier is used in the calibration unit. A dc amplifier operating in the electrometric mode is connected between the register and recorder (see Fig. 1).

TITLE: Effect of technological orientation of structure on the wear of polytetrafluoroethylene

SOURCE: Fiziko-khimicheskaya mehanika materialov, v. 2, no. 6, 1966, 698-701

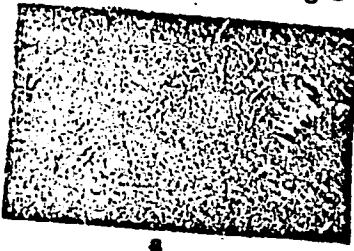

TOPIC TAGS: polymer structure, polytetrafluoroethylene, wear resistance, chain

ABSTRACT: The wear resistance of polytetrafluoroethylene (PTFE) is investigated as a function of the pattern of alignment of supramolecular formations, which pattern is determined by the technique of processing of the polymer into manufactured articles. The product of the polymerization of PTFE represents a white powder with a fibrous structure which is processed into manufactured articles by pressing and sintering at 360-370°C. The specimens tested were cylinders 30 mm in diameter and 40 mm in height, pressed by means of uniaxial compaction. Such a force field leads to an orientation of supramolecular structures which will persist during subsequent sintering owing to the extremely high viscosity of the PTFE melt. Two series of specimens were tested

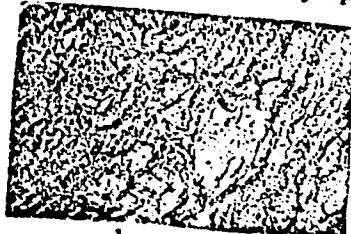

Card 1/3

ACC NR: AP7004189

for wear. In the first series (Ic) the planes of working surfaces were at right angles to the pressing axis and in the second series (IIc), parallel (Fig. 1). It was found that specimens Ic (perpendicular) are represented by laminar formations, whereas specimens IIc (parallel) exhibit edges of these laminar formations. Further, specimens IIc

a

Card 2/3

ACC NR: AP7004189

wear out more intensely, which is apparently associated with the greater number of structural defects at such an orientation of the supramolecular formations. Similarly, a rise in temperature acts more destructively on specimens with a structure of the IIc type. This difference in wear resistance can be offset by adding colloidal graphite as a filler during sintering or by partially pulverizing the sintered polymer so as to partially destroy the molecular chains and thus to equalize the structure in the transverse and longitudinal directions. TITLE: Effect of mineral additives on polycaprolactam crystallinity

SOURCE: AN UkrSSR. Modifikatsiya svoystv polimerov i polimernykh materialov (Modi-
fication of the properties of polymers and polymeric materials). Kiev, Naukova dum-
ka, 1965, 96-99

TOPIC TAGS: polymer, crystalline polymer, polymer structure, solid mechanical pro-
perty, synthetic material

ABSTRACT: The effect of SiO_2 -marshallite, Al_2O_3 -corundum, TiO_2 -rutile, and Fe_2O_3
on the physico-mechanical and structural properties of polycaprolactam was investi-
gated. Crystallinity was examined using 3 mm^2 samples and a UEMV-10 electron micro-
scope with 8,000-10,000 magnification. Tensile strength was measured on standard
samples of $2 \times 4 \times 55 \text{ mm}$ and the transverse strength was measured on $4 \times 6 \times 55 \text{ mm}$

Card 1/2

bars using the FM-500-machine (manufactured by the Rauenstein Company). Mineral additives with an average particle diameter of 1-50 microns were added either during the polymerization process or into the finished polycaprolactam. It was found that all these mineral additives promote crystallinity in polycaprolactam, and improve the mechanical properties of the products. The effect of mineral additives on physico-mechanical properties of polycaprolactam is shown in table 1. Orig. art. has: 18 figures, 2 tables.

Biological Chemistry

Pharmacological study of amorphous glycosides from leaves of *Erysimum cheiranthoides*. P. I. Bernik and Research Chem.-Pharm. Inst., Krasnoyarsk. *Zh. Toksikol.*, 16, No. 5, 43 (1953). The bio-activity of *E. cheiranthoides* glycosides is 5500 cat units or 55,000 toxic units; intravenous injection gives the greatest effect. Peroral absorption is nearly complete in 3 hrs., and elimination is rapid (0.016 mg./kg./hr.) when introduced into the duodenum of cats. There is very little cumulative effect. Julian F. Smith

In an article entitled "Ergotal--a New Ergot Preparation," N. G. Sinilova and P. I. Bezruk, Kharkov Scientific-Research Chemico-Pharmaceutical Institute, describe the new ergot preparation developed in 1954 at the Kharkov Scientific Research Chemicopharmaceutocal Institute. Ergotal is a white with a brownish tint powder; has a faint characteristic odor; slightly soluble in water, less soluble in organic solvents, and readily soluble in acidified water. It contains not less than 96 percent of ergot alkaloids in the form of water soluble and nonwater soluble phosphates. An identity test revealed that Ergotal contains mainly the ergotoxine group of alkaloids: ergocristine, ergocryptine, and ergocornine. Only traces of ergotamine alkaloids are found. Ergotal is considerably less toxic than either ergotine or the fluid extract of ergot. The smallest lethal dose of ergotal is 2 milligrams per 20 grams of body weight of mice, while the smallest lethal dose of ergotine is 0.5 milliliters and of the fluid extract of ergot -- one milliliter per 20 grams of body weight of mice. It can be successfully applied in all cases in which other ergot preparations are indicated. It is contraindicated during pregnancy, birth, or in uterine fibromyoma. Abstract: acid in the liver, heart and skeletal muscles of the experimental animals was found to be lower than in healthy animals. I, in concentration of 1:15-1:18 million had a toxic effect upon the isolated heart of the diphtheritic animal, while in the control group, it produced increase of the amplitude and slowing of the rhythm. A therapeutic effect was noted at a concentration of 1:60 million. One part of the animals received, parenterally, for a period of 5-6 days, 20 mg/100 g doses of ascorbic acid with the first day of infection. These guinea pigs survived injection of I at a rate of 0.05 mg/kg per 1 hour, while the control animals, having also received ascorbic acid, survived injections of 0.17 mg/kg per 1 hour. I showed therapeutic action on the isolated heart

Title : The Influence of Corezim on Cardio-Vascular System.

Orig Pub : Farmakol. i toksikologiya, 1958, 21, No 4, 38-42

Abstract : In Experiments on dogs, corezim (I; 0.01-0.05 mg/kg) increases the blood pressure insignificantly, induces a slowing down of rhythm, increase of cardiac contraction amplitude, increase of systolic and minute volume. With an increase of the dose of I a sharp increase of blood pressure, acceleration of rhythm, arrhythmia and decrease of amplitude are observed. Under the influence of small doses of I on ECG of cat, a slowing down of the rhythm and a decrease of the systolic index was noted. In introduction of toxic doses of I, the positive T- wave passes into the negative, the S-T interval is displaced,

TITLE: Universal through-power meter (wattmeter)

SOURCE: Pribory* i tekhnika eksperimenta, no. 4, 1964, 111-116

TOPIC TAGS: wattmeter, power meter, RF power meter, electronic power meter

ABSTRACT: Intended for high-speed power measurements, such as those employed in r-f field-plasma experimentation, the instrument is based on a multigrid converter tube which yields the $IU \cos\varphi$ function. To reduce the error due to nonlinearity of the working parts of the tube anode-grid characteristics, the phase of one of the r-f grid voltages is periodically (with a constant frequency 50 or 200 kc) shifted by 180° . A functional block diagram and simplified

connection diagram are presented. The instrument indicates peak values and permits visual observation of active-power, voltage, and current pulses (3 oscilloscopes provided) in a load whose parameters fluctuate in time. The instrument has been developed in two versions: for 0.2-2 Mc range and for 1-10 Mc range. Rated peak currents are 50-1,000 amp; peak voltages, 2-20 kv. Frequency spectrum of the measurand power: 0-15 kc in the first version and 0-60 kc in the second. After excluding a "frequency error" by using a correction table, the over-all error remains within 10%. "The authors wish to thank V. N. Goncharova for her extensive work in building an experimental lot of the instruments, and V. G. Petriashvili for his/her help in preparing the technical documentation." Orig. art. has: 4 figures and 4 formulas.

AUTHORS: Markovskiy, L. Ya. and Bezruk, Ye. T.

TITLE: The chemical stability of some transitional metal borides (II).

PERIODICAL: Zhurnal prikladnoy khimii, v. 35, no. 3, 1962, 491-498

TEXT: In continuation of earlier work the authors studied the chemical stability towards acid hydrolysis of the different borides of Mn, Cr, Fe, Ni and Co to establish a relationship between boride stability towards hydrolysis and boron contents of the compound. To this end, Mn_2B , MnB , Mn_3B_4 , MnB_2 , FeB , Fe_2B , CoB , Co_2B , Co_3B , NiB , Ni_4B_3 , Ni_2B , Ni_3B , CrB , Cr_5B_3 and Cr_2B were synthesized from the elements, treated with a 1:2 HCl solution, and their reaction products analyzed for diborane, tetraborane and hydrogen. It was shown that boranes and hydrogen were formed in each case. The gradual increase of B contents in every group is connected with a sharp decrease in the rate of decomposition, as well as in borane formation.

The stability of isostructural borides increased from Cr to Ni. The increased stability of boron-rich compounds was interpreted in terms of correspondingly increasing strength of B-B bonds. There are 2 figures, 6 tables and 20 references: 10 Soviet-bloc and 10 non-Soviet-bloc. The 4 most recent references to the English-language publications read as follows: Binder and B. TITLE: Fusibility diagram and some chemical properties of borides in the manganese boron system

SOURCE: Zhurnal prikladnoy khimii, v. 38, no. 8, 1965, 1677-1682

TOPIC TAGS: manganese, boron, boride, oxygen, nitrogen, ammonia, carbon, phase diagram

ABSTRACT: The work is intended as a study of the chemical properties of individual boride phases, particularly their interaction with oxygen, nitrogen, ammonia, and carbon. Manganese borides were prepared by sintering briquetted mixtures of powders of electrolytic manganese (99.5% manganese) and refined boron (98.5%) in corundum furnaces in an atmosphere of purified argon. Temperature limits for the formation of different boron phases, sintering conditions and composition of the samples are given in tabular form. After heating, the samples were cooled along with the furnace. The following boride phases were observed: Mn_2F , MnB , Mn_3B_4 , and MnB_2 . In long term tests with a large excess of metal-
